Homoidea

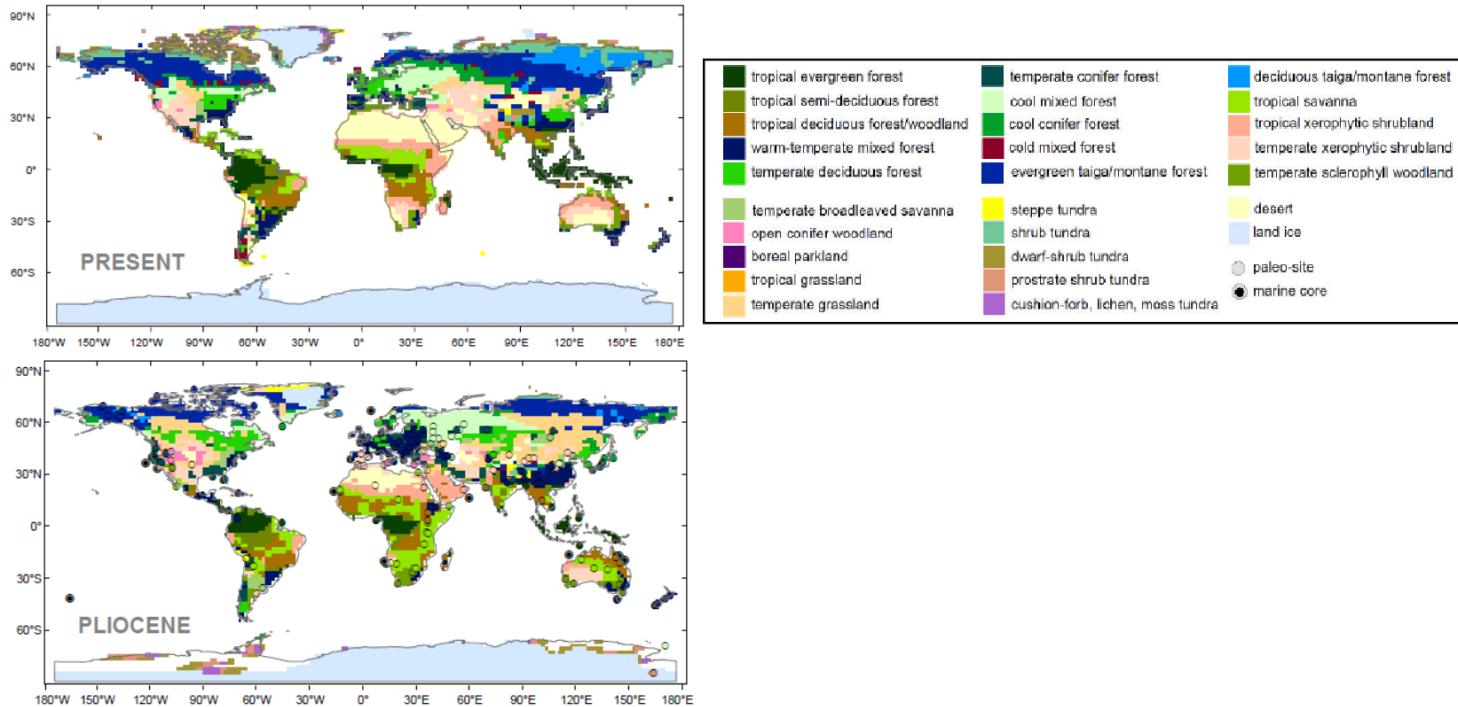

Zoom in on Hominini

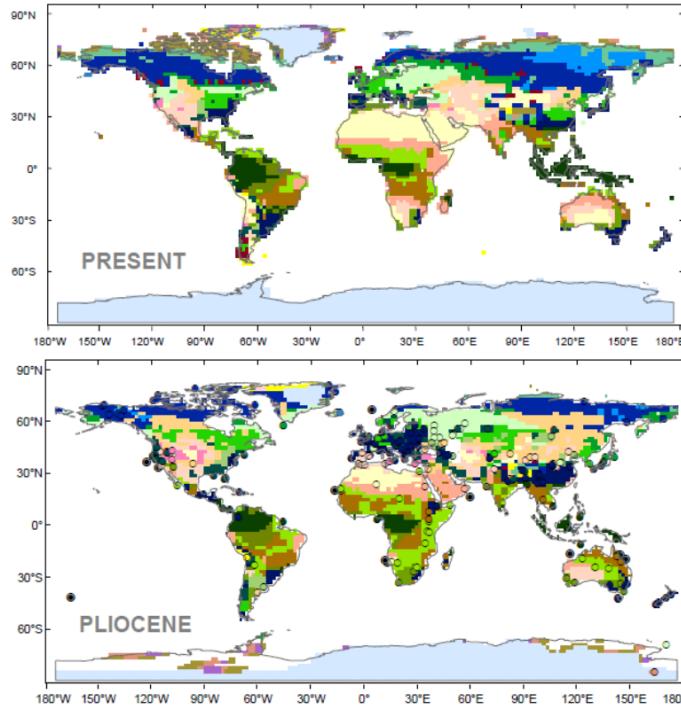

Note the Pliocene-Pleistocene transition

The Pliocene (5.3-2.6 mya) was warm ...

... about 2-4 °C warmer ...

Is this our future?

NHG = Northern Hemispheric Glaciation

Leading to Pleistocene (~2.58 mya – 11.7 kya)

Pulses of major expansion of glaciation (*Ice Ages*) and retreats

Nomenclature near-fail: *Pliocene* means "new age", *Pleistocene* means the "newest age", *Holocene* means "entirely new" ... which, really!?

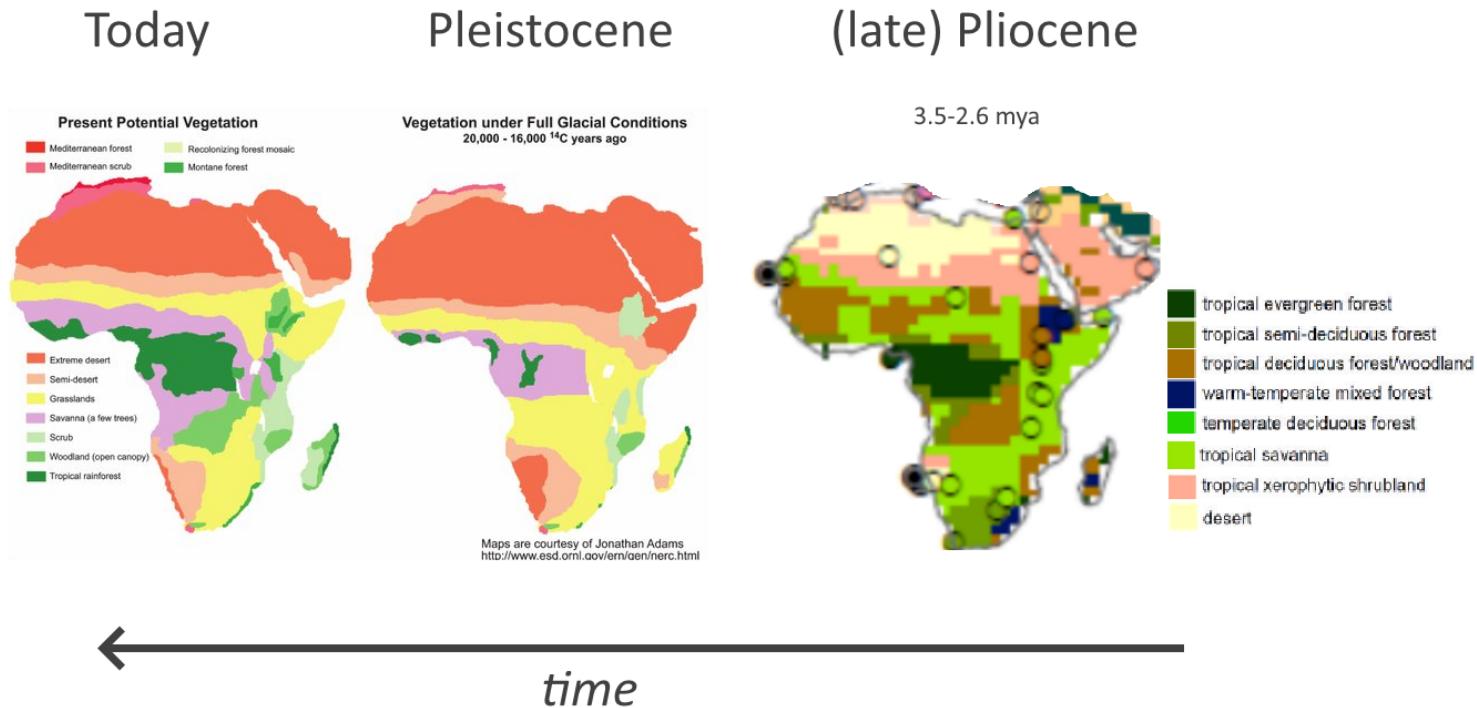

Pleistocene famously the age of mammalian giants

Brief intro to one biome: The Mammoth Steppe

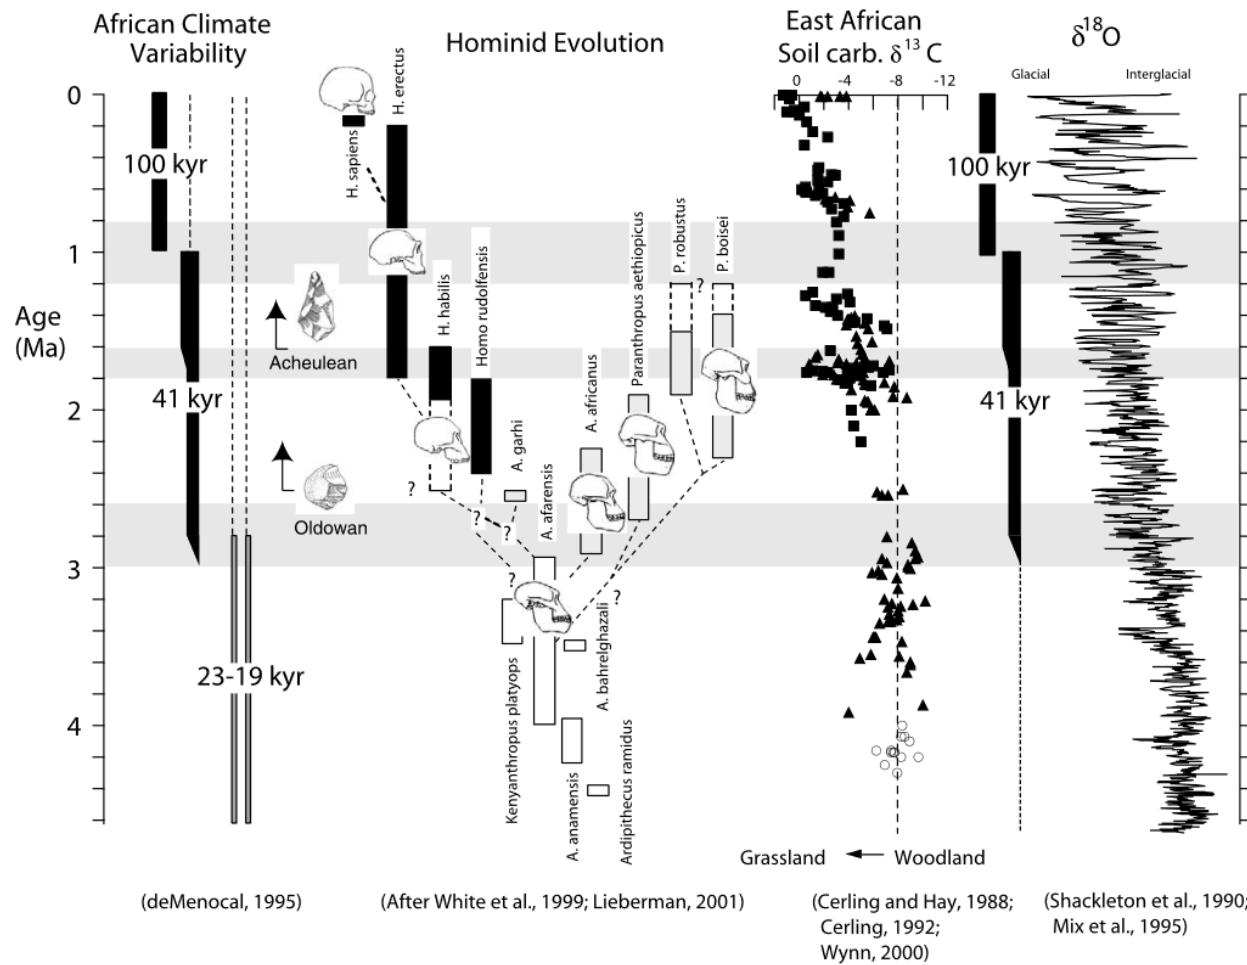

What does this mean for hominids?

- **Africa** becomes LESS forested more steppe / savannah / grassland.
- **Explosion** of large herbivore (grazing) populations

Cooling -> Grasslands -> Herbivore Speciation -> Hominid divergence

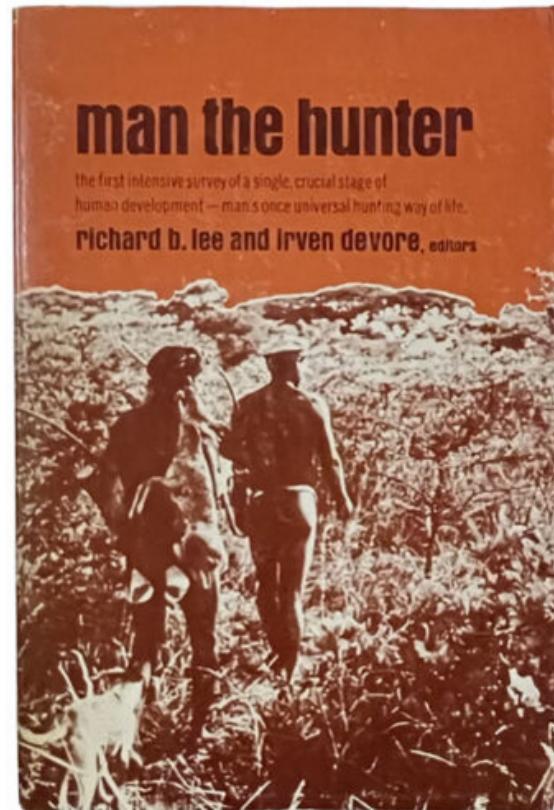

Ever since Darwin ...

the main idea has been:

1. hominid ancestors abandoned trees ...
2. became bipedal ...
3. used free hands to make tools ...
4. which they used to **hunt** ...
5. which stimulated language / cooperation / civilization, etc.

corrolaries

1. males hunt (and are stronger/smarter/etc.)
2. females gather

Alternative more nuanced hypothesis ... *scavenging*

During Pliocene - Pleistocene transition, increased seasonality in precipitation lead to vegetative food-source bottlenecks.

Food diversification turned *Paranthropus* to exploit seeds, roots, sedges ... *Homo* turned to meat carcasses left behind by large carnivores.

Evidence includes:

- (1) the fact that most early tools are **butchering** tools not **hunting** tools.
- (2) Predators of large herbivores almost always leave plenty to scavenge.
- (3) Scavenging is **easier**, even without fancy tools.

Consequence: Cooperation and communication and rapid divergence from other early hominids.

Either way ... eventually humans became VERY good hunters

including (apparently) plenty of females

Pleistocene
extinct

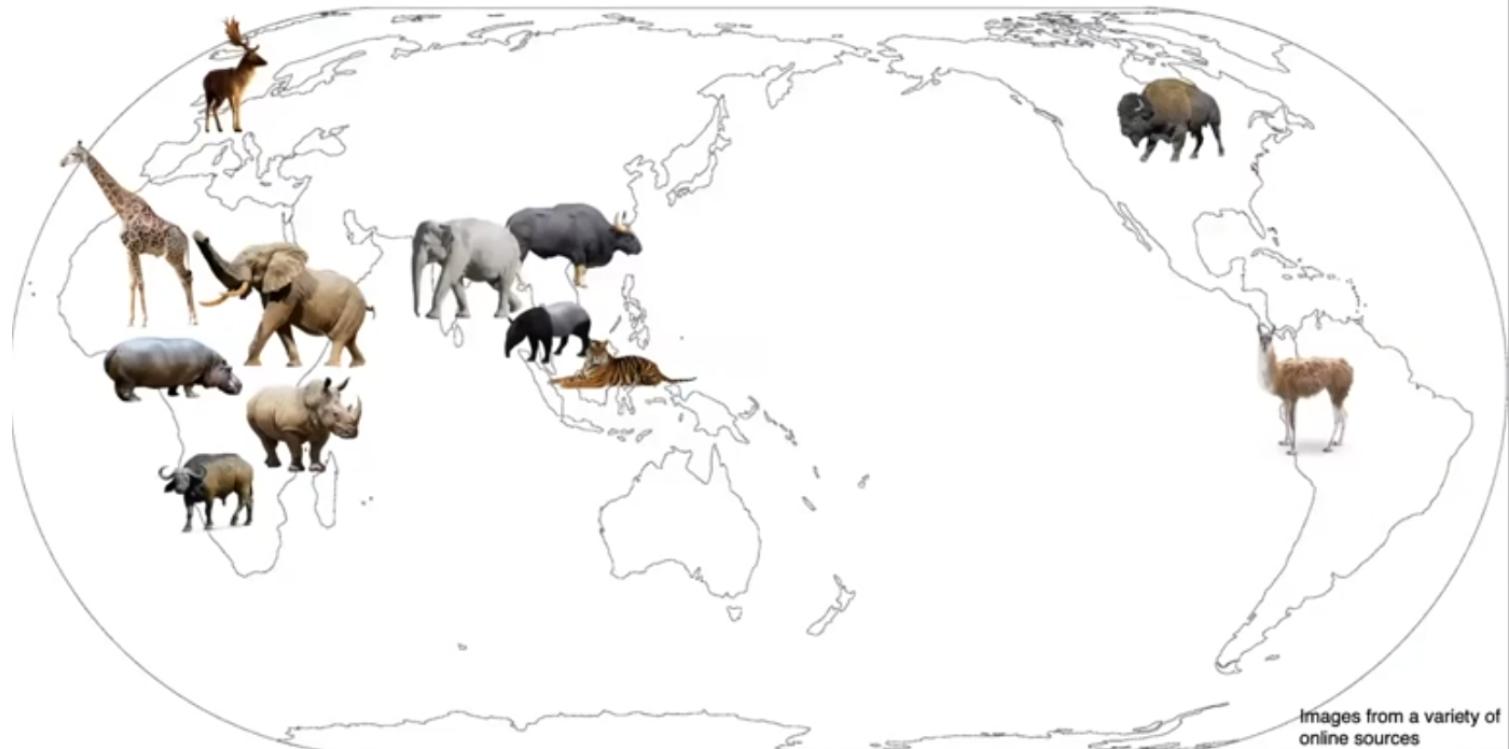

Compare location of extinct megafauna

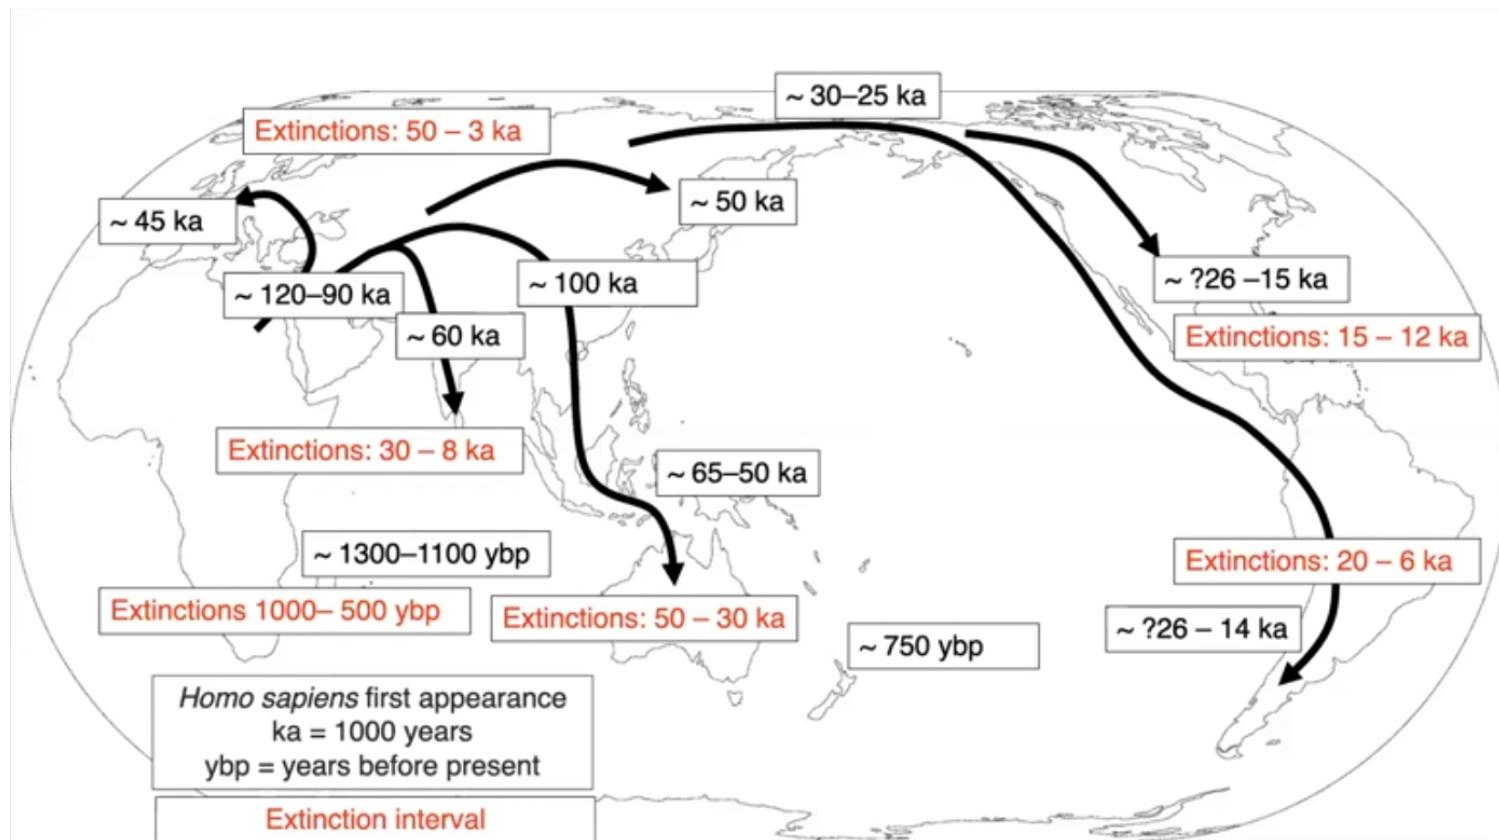

50,000 years ago, large species, especially large mammals lived everywhere

To extant megafauna

Global human dispersal ... followed by extinctions

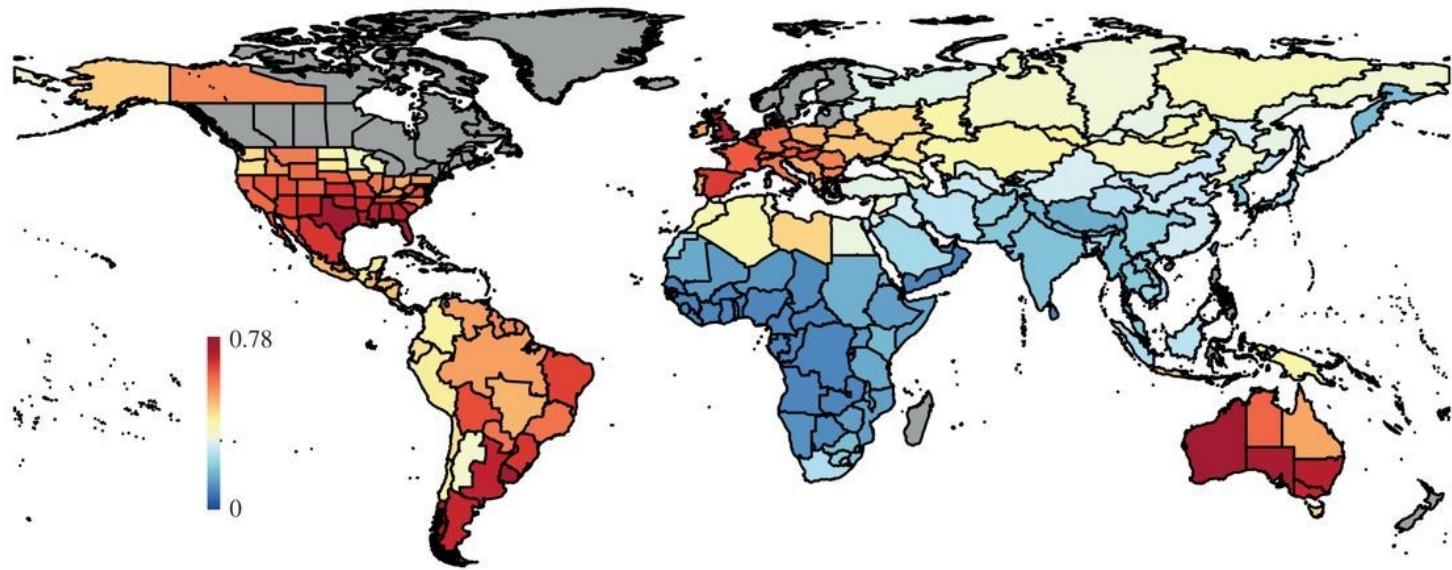

Was it humans or climate?

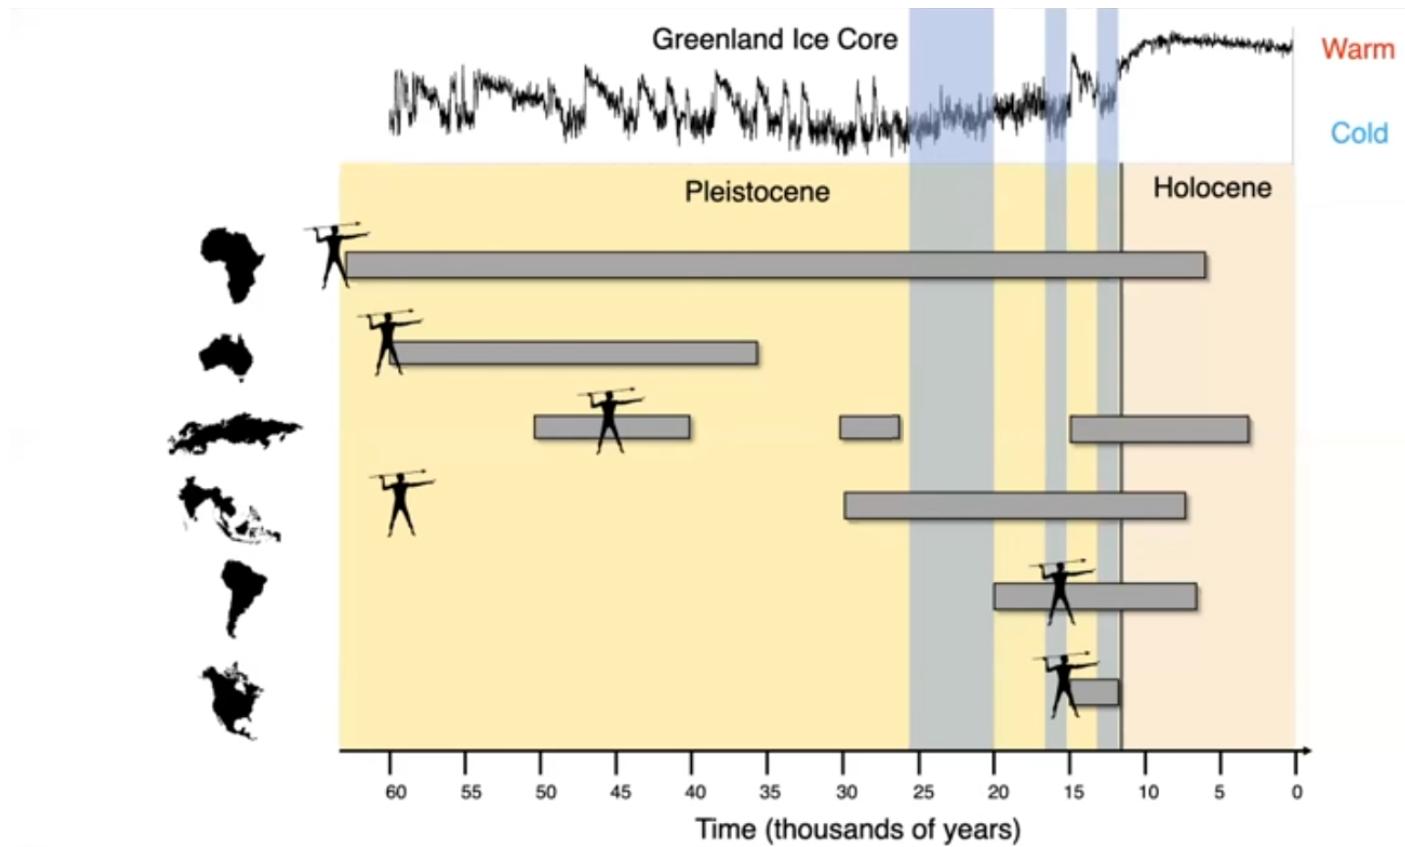

(start at 2:46)

Longer co-existence -> relatively less extinction

region	extinction (genera)
- Subsaharan Africa:	4.5% (2 / 44)
- Indian Subcontinent:	13.8% (4 / 29)
- Europe:	30.4% (7 / 23)
- North America:	73.3% (33 / 45)
- South America:	79.3% (46 / 58)
- Australia and New Guinea:	93.8% (15 / 16)

Climate and/or humans?

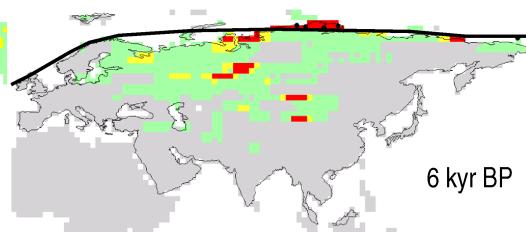

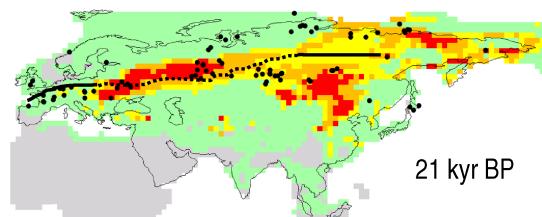

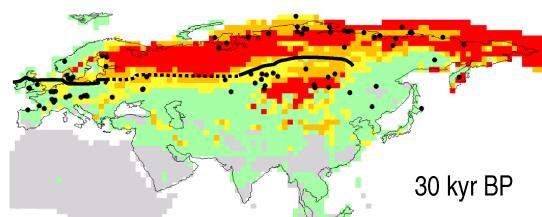

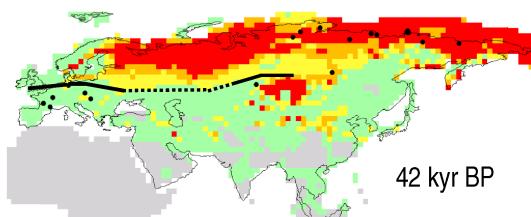

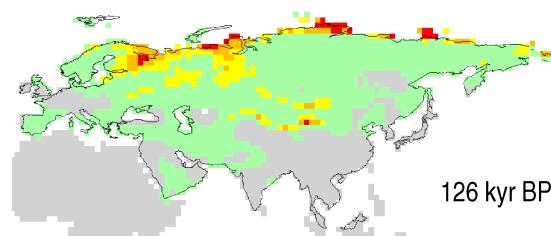

(kind of a smoking ... spear?)

Does climate play *somerole*?

warm period ...
mammoth survives

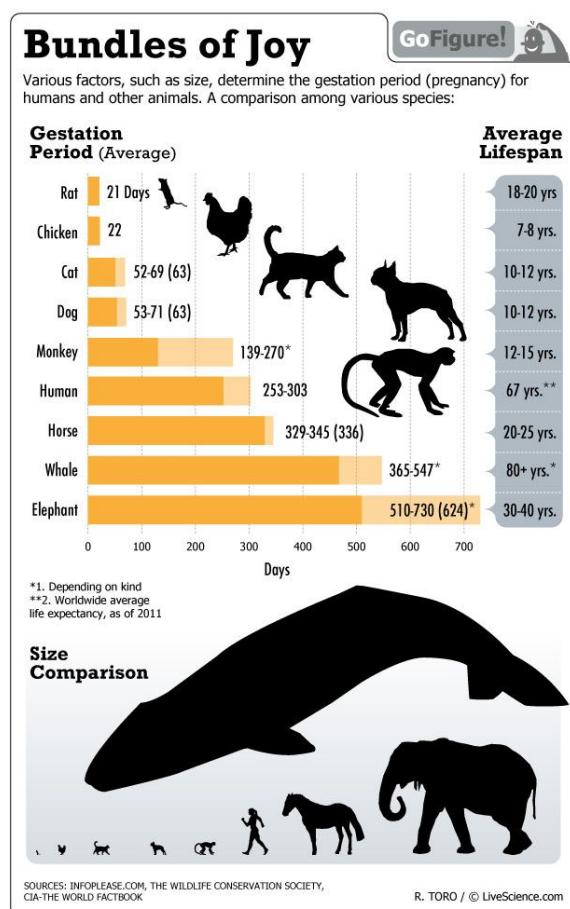

warm period ...
mammoth goes
extinct

Woolly Mammoth (*Mammuthus primigenius*) habitat fragmentation ... leads to higher **risk** when human X-factor arrives.

Does size play a role?

- Long gestation time
- Long inter-birth intervals
- Small litters
- Delayed age to maturity

Also leads to higher **risk** of extinction once human X-factor arrives.

Take-aways ...

Hominids **are** animals, and have obviously always interacted ecologically with other animals.

Climate-driven changes in vegetative ecology led to a major shift in diets towards meat and marrow, and major consequences for hominid evolution. (With debate was it **hunting or scavenging**)

In combination with **climate change and reproductive biology/physiology**, even small numbers of humans can cause major extinctions. (with debate as to the relative importance of **hunting vs. climate change**)

On places with long histories of co-evolution (esp. Africa) historic humans were able to coexist with highly diverse megafauna.

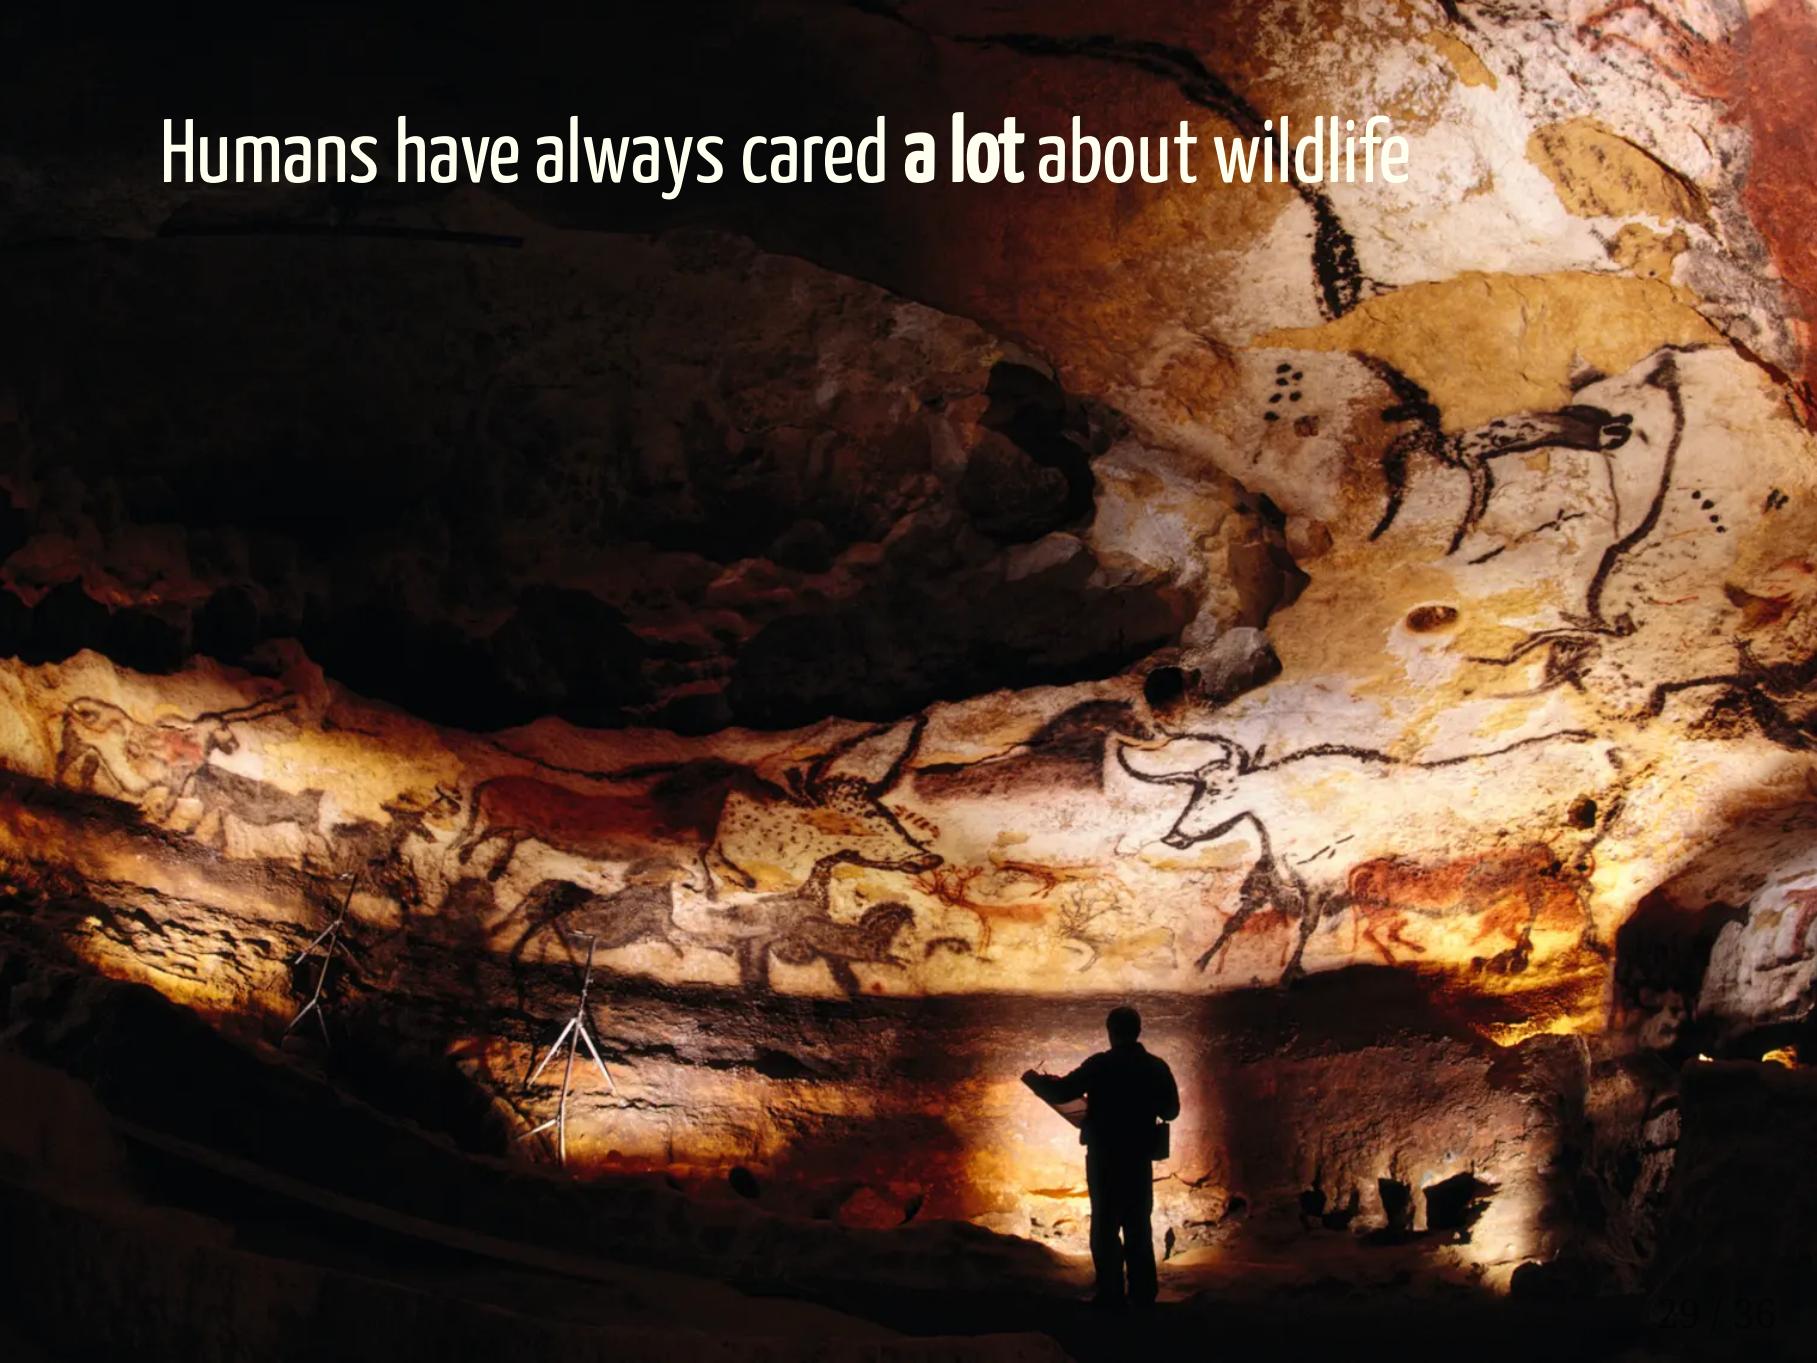

Take-aways re. science

Paleontology (paleoecology, paleaoclimatology, etc.) requires:

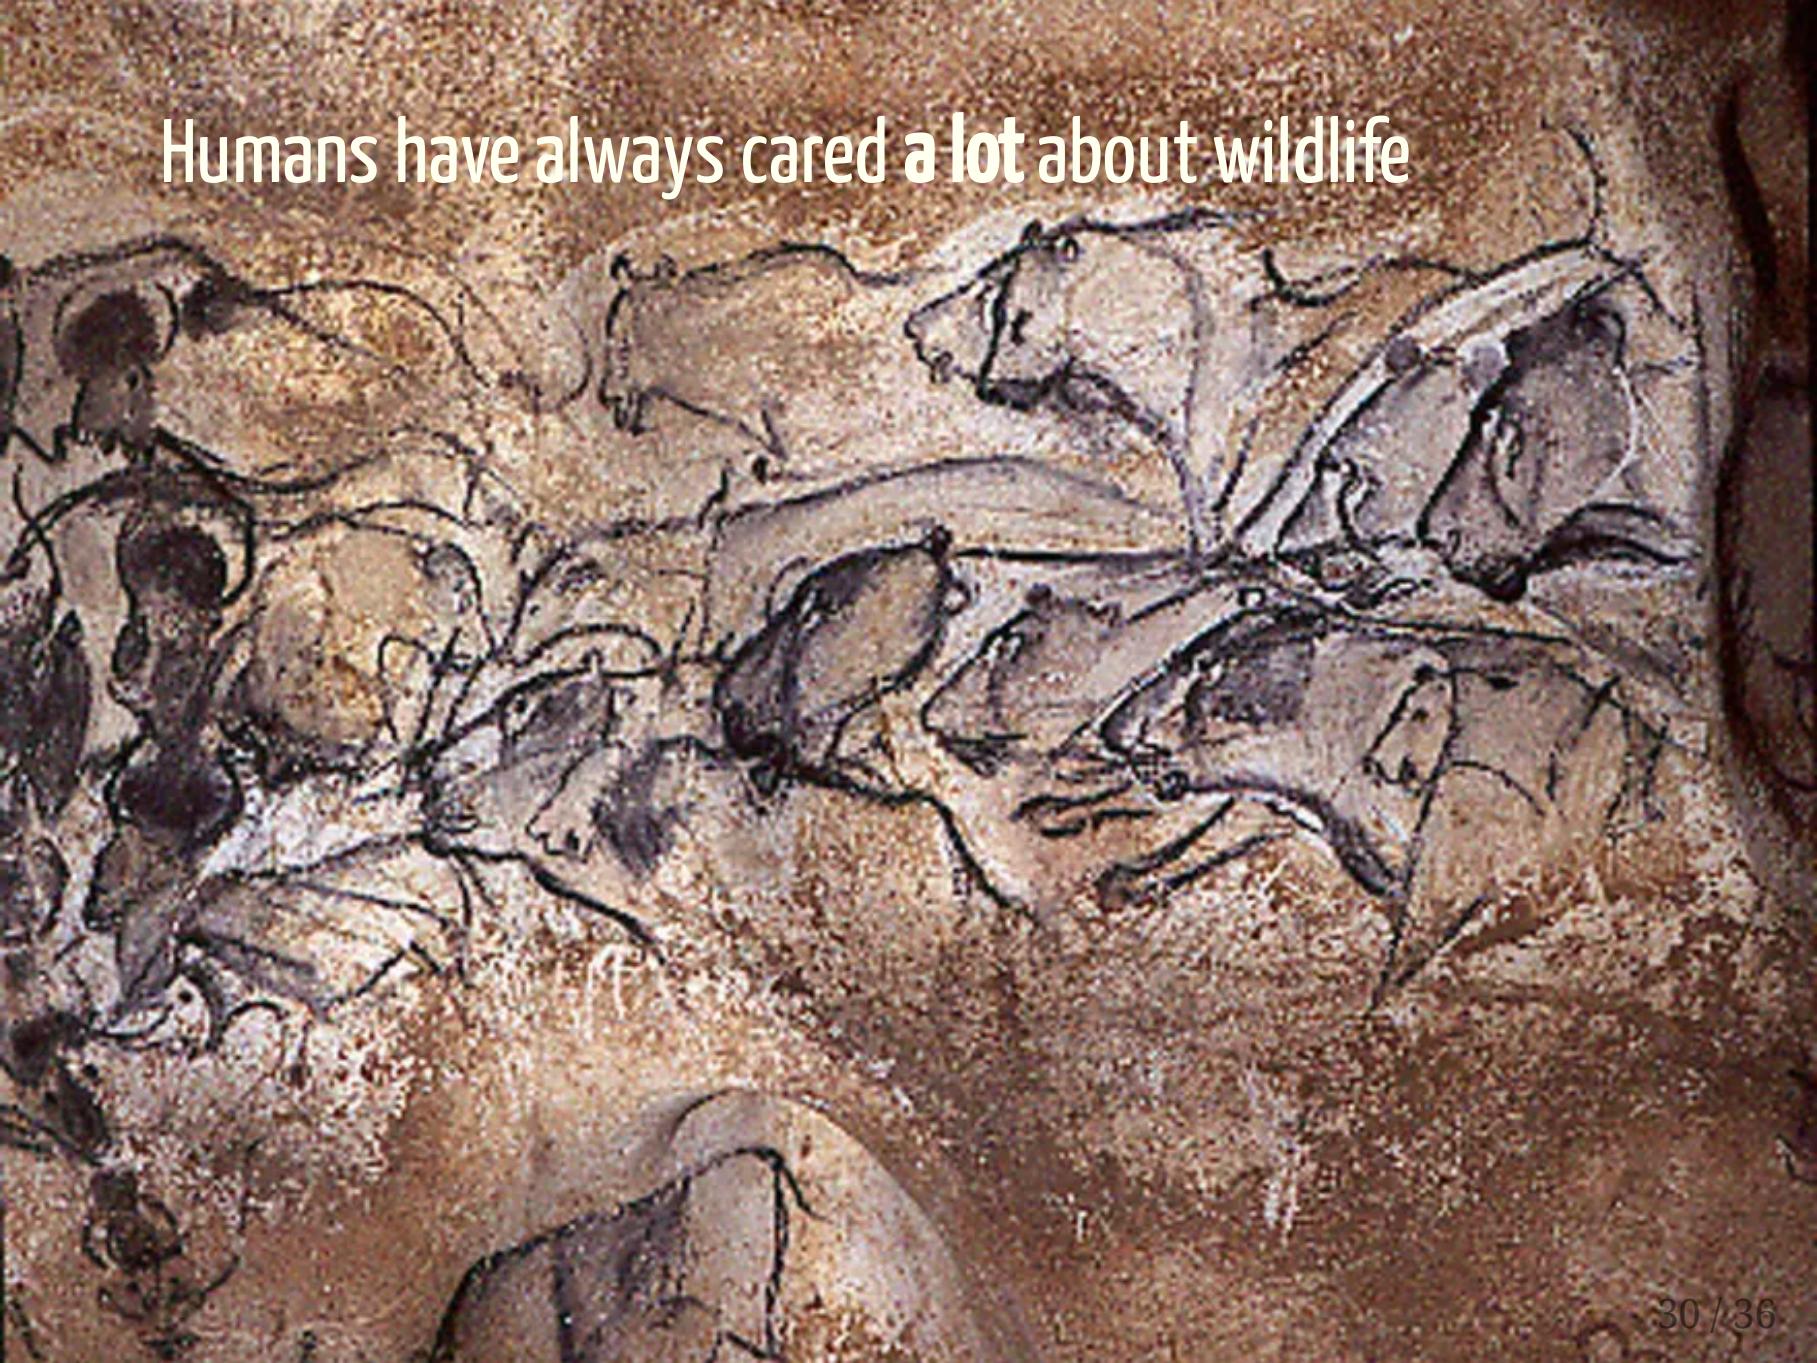

- HIGHLY patchy, incomplete and hard to obtain and interpret data (esp. **fossil remains**)
- fancy **technology**, esp. for dating, reconstructing climate and, increasingly, DNA sequencing.
- sophisticated **modeling** of (global) climate & vegetation
- understanding of climatology, biogeochemical cycles, global ecology, basic ecology, human and animal behavior (for **modern analogues**).
- Lots and lots of guesswork, argument building, and debate!

In the end - obviously - there is **lots** we'll never know, but it is **impressive** the stories that can be inferred!

Humans have always cared **a lot** about wildlife

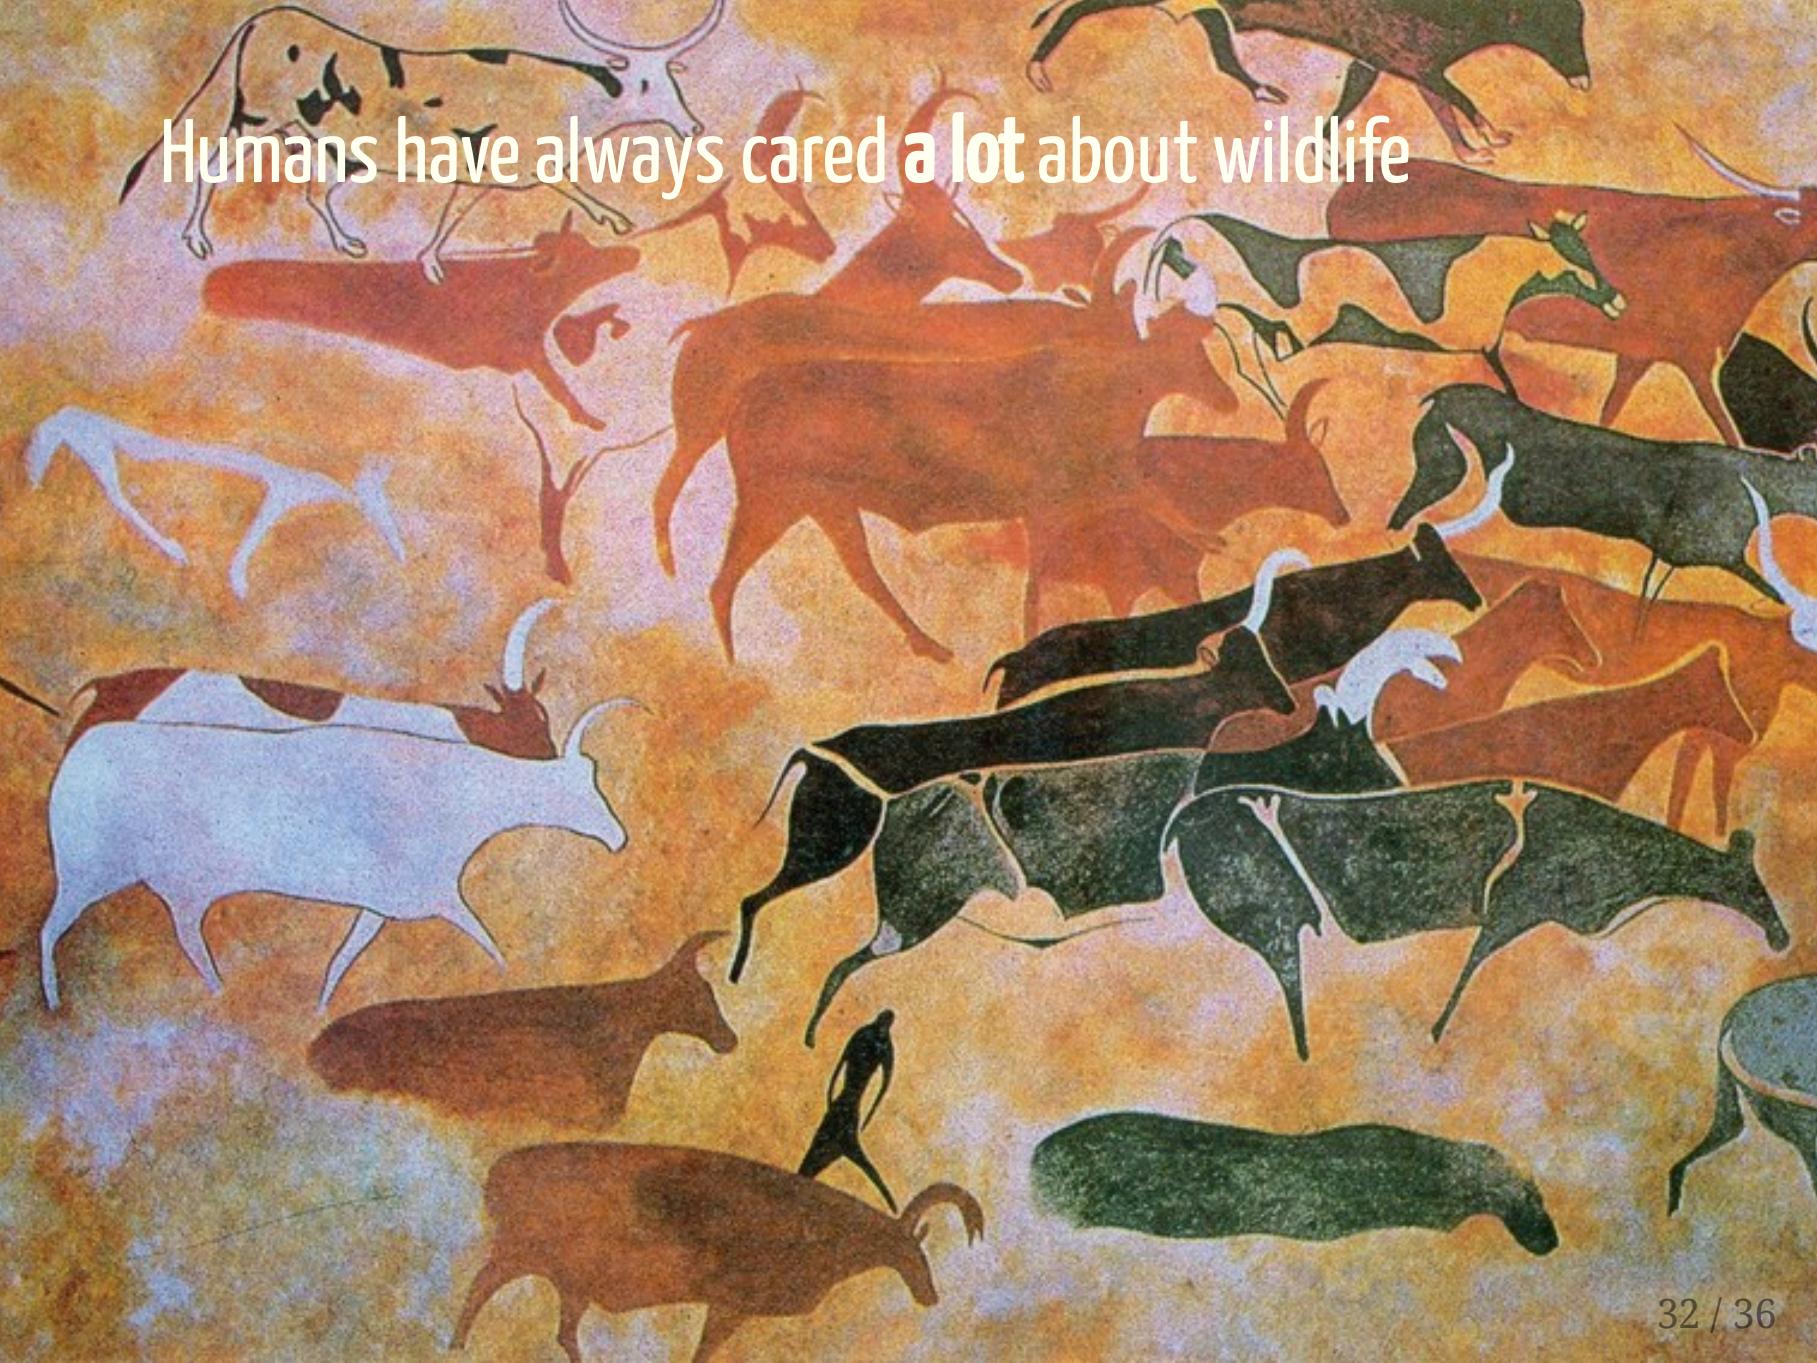

Humans have always cared **a lot** about wildlife

Humans have always cared **a lot** about wildlife

A reproduction of the Chauvet Cave painting, a prehistoric rock art site in France. The image shows a dense assembly of animal figures, primarily horses and deer, rendered in various colors like brown, orange, red, and black. The animals are depicted in dynamic poses, some running and jumping, others standing or grazing. The style is characteristic of Paleolithic cave art, using bold outlines and flat color washes.

Humans have always cared **a lot** about wildlife

Humans have always cared **a lot** about wildlife

Much higher-level question ...

Can we leverage our paleo-ecological knowledge to mitigate climate change?
